Introduction: The measurements of the real (ϵ_1) and the imaginary (ϵ_2) parts of the dielectric function (DF) over a complete momentum (q) - energy (E) range provide a crucial basis for studies of radiation in matter. Unfortunately, knowledge of the DF for molecular liquids is quite insufficient, especially for $q \sim 1$, because of the lack of appropriate experimental tools. With the developments of synchrotron radiation sources, however, it is now possible to apply inelastic x-ray scattering (IXS) to determine the DF of molecular liquids for $q < \sim 1$.

Methods and Materials: IXS spectra for the π - π^* excitation of liquid benzene have been measured for $0.35 < q < 1.5 \text{ \AA}^{-1}$ at the X21, with 0.5eV-resolution for $E < 10 \text{ eV}$ to resolve the π - π^* peak and 1.3eV-resolution for $E > 10 \text{ eV}$ to achieve high S/N ratio.

Results: The ϵ_1 and the ϵ_2 of benzene were deduced from the IXS spectra via the Kramers-Kronig transformation, and were shown in Fig. 1. Although the π - π^* peak in the IXS profiles shows a negative q -dispersion ($\sim 0.5 \text{ eV}$), no marked peak dispersion is found for the ϵ_2 , indicating that the π - π^* excitation in liquid is well localized. On the other hand, the amplitude of the variation in the ϵ_1 is reduced significantly as q increases. Thus the negative dispersion in the IXS spectra must be attributed to changes of the shielding factor, $\epsilon_1^2 + \epsilon_2^2$. This result means that the experimental deduction of not only energy-loss spectra but also DF on target molecular condensates is indispensable.
